Projects

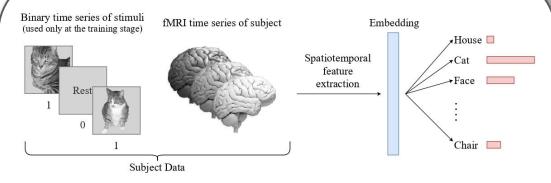

Pairs of images obtained from each other by simple manual operations (like grayscaling) are considered similar, class 1

Other pairs of images belong to class 0, even if their content is close, or the same object is depicted, but from different angles.

Seminar → Detection

Next Lecture → Segmentation

Classical approach: SIFT vectors

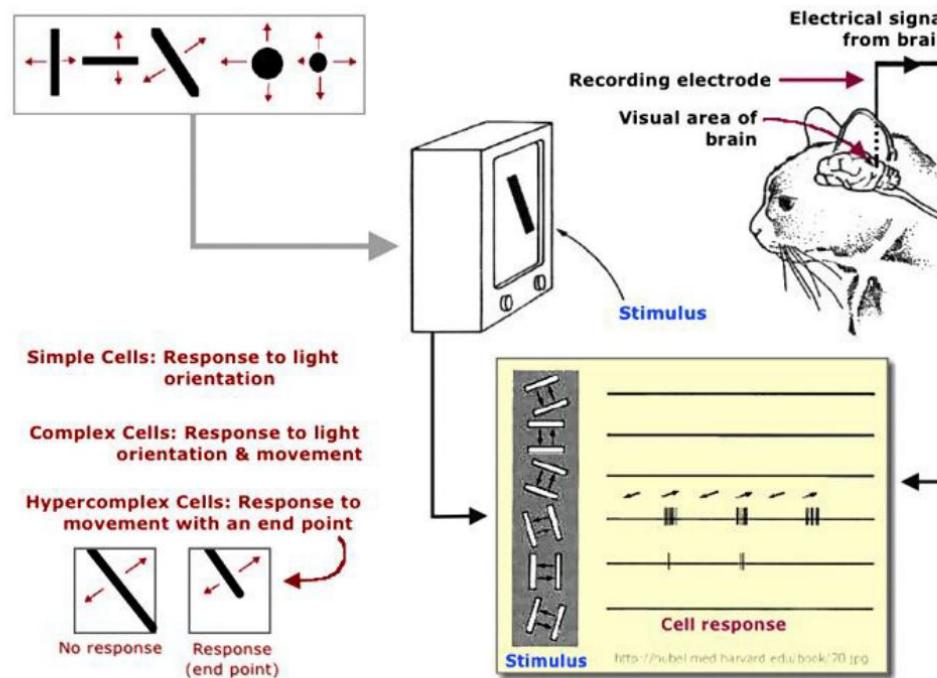

We should somehow extract features from images to build a classification model or match images.

Question: How can we do it?

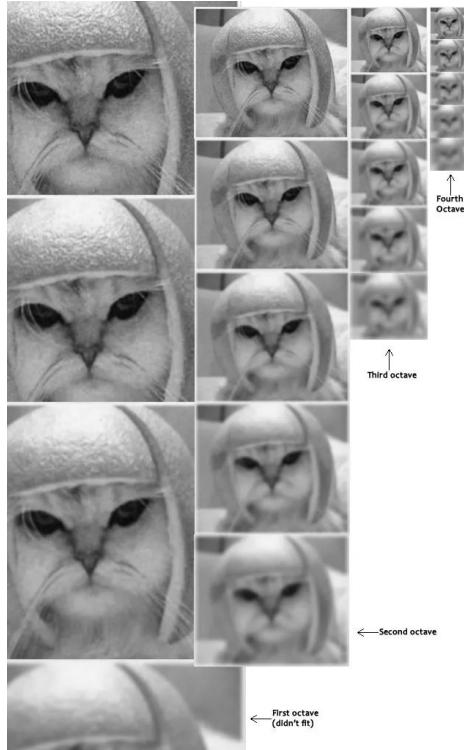

[Distinctive Image Features from Scale-Invariant Keypoints \(2004\)](#)

Why edges are important?

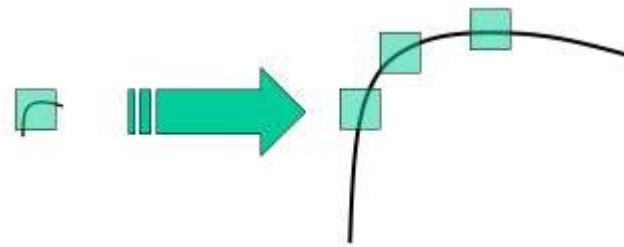

Hubel & Wiesel, 1959

SIFT vectors

Real world objects are meaningful only at a certain scale. You might see a sugar cube perfectly on a table. But if looking at the entire milky way, then it simply does not exist.

This multi-scale nature of objects is quite common in nature. And a scale space attempts to replicate this concept on digital images.

The basic concept of the image is edge, let's start by extracting edges

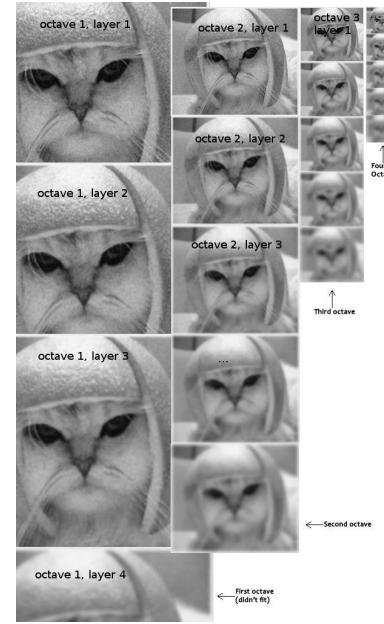

<https://www.ultralytics.com/ru/blog/what-is-the-scale-invariant-feature-transform-sift>
<https://blog.roboflow.com/sift/>

Classical approach: SIFT vectors

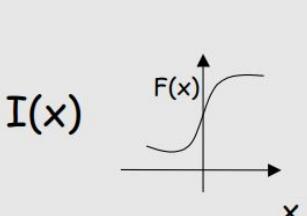

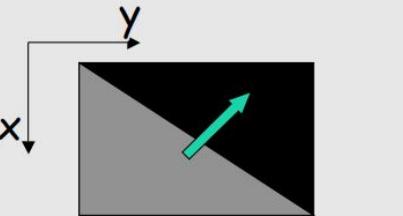

Using gaussian kernel to remove noise.

Gaussian filter: $G(x, y) = \frac{1}{2\pi\sigma^2} \exp\left(-\frac{x^2+y^2}{2\sigma^2}\right)$, **convolution:** $I'(i, j) = \sum_{k,l} I(i+k, j+l) G(k, l)$

Then, repeat the operations on lower scale

Edge Detection Summary

1D	2D
<p>step edge</p> 	<p>$I(x, y)$</p> 
<p>1st deriv</p> $\frac{dI(x)}{dx} > Th$	$ \nabla I(x, y) = (I_x^2(x, y) + I_y^2(x, y))^{1/2} > Th$ $\tan \theta = I_x(x, y) / I_y(x, y)$
<p>2nd deriv</p> $\frac{d^2I(x)}{dx^2} = 0$	$\nabla^2 I(x, y) = I_{xx}(x, y) + I_{yy}(x, y) = 0$ <p>Laplacian</p>

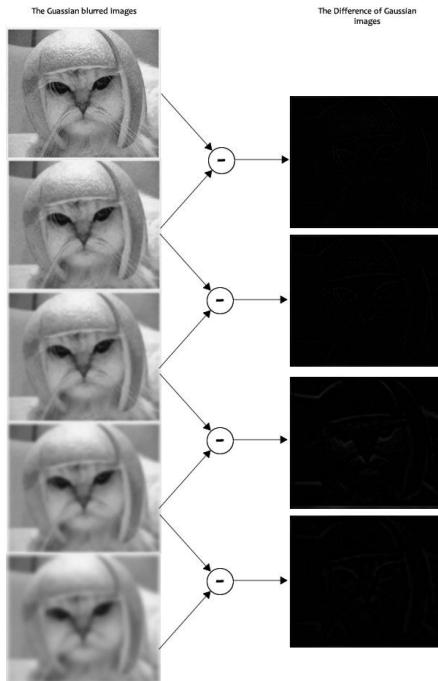

Laplacian of Gaussian (LoG)

Laplacian of Gaussian locates edges and corners on the image. These edges and corners are good for finding keypoints.

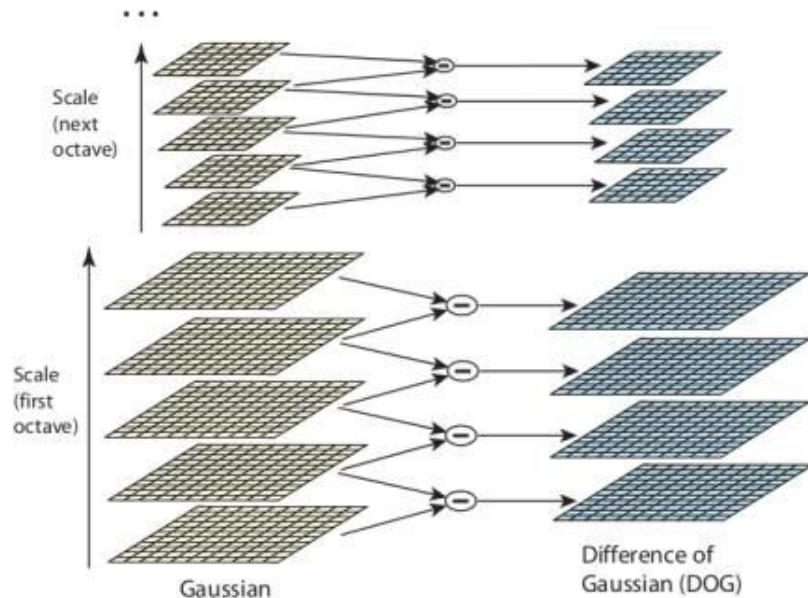

But it is computationally hard calculate. One can use simple approximation using **difference of Gaussians**.

LoG result

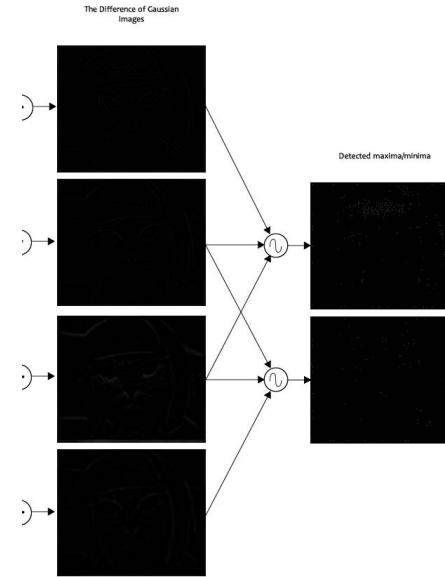

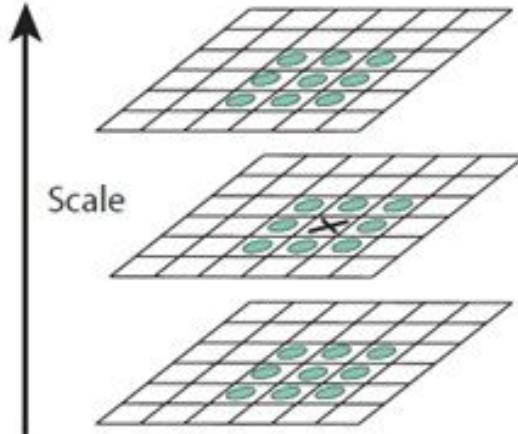

What we will get?

Repeating procedure over scales

Finding keypoints

Next, to find keypoints we are looking for maximum and minimum. The author propose the following scheme: we compare the pixel marked with cross with all his 26 neighbours (left picture).

As we got 4 octaves (images) we can obtain 2 image with keypoints.

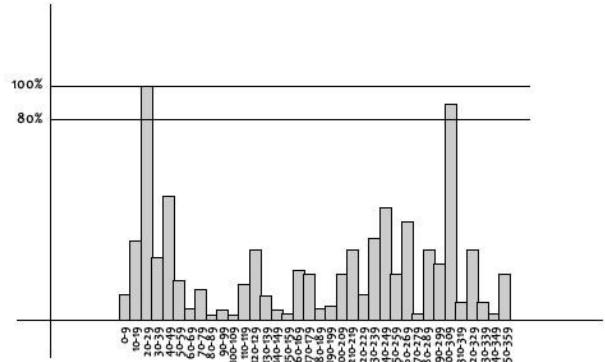

Orientation Assignment

The next thing is to assign an orientation to each keypoint. This orientation provides rotation invariance. The more invariance you have the better it is. Actually, it is very important when we do matching between different images. The same object can have different orientation. To calculate the orientation we use the following formulas:

$$m(x, y) = \sqrt{(L(x + 1, y) - L(x - 1, y))^2 + (L(x, y + 1) - L(x, y - 1))^2}$$

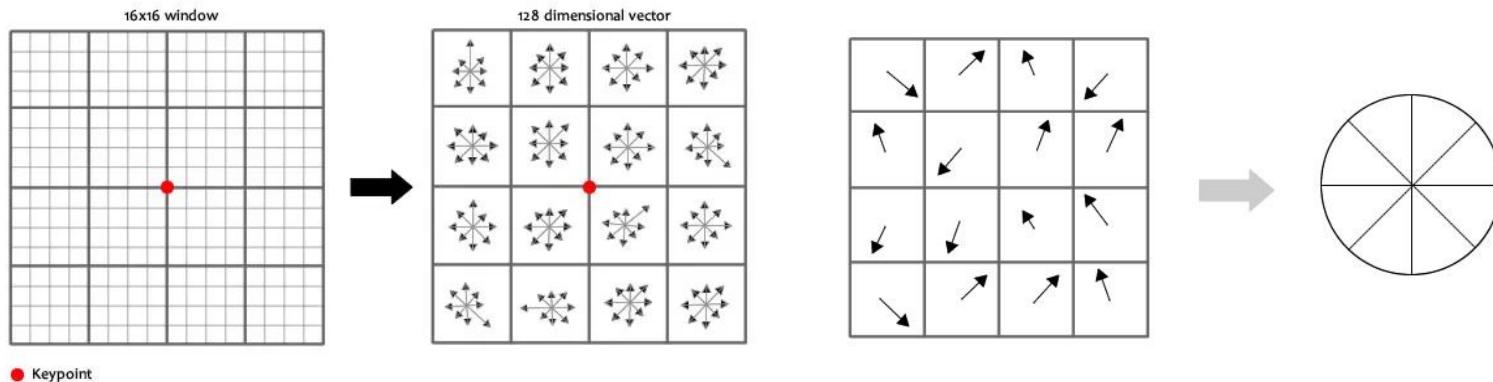

$$\theta(x, y) = \tan^{-1}((L(x, y + 1) - L(x, y - 1)) / (L(x + 1, y) - L(x - 1, y)))$$

Then, we create a histogram with magnitude distribution. If distribution of current keypoint is more than 80% than we consider it as new keypoint

Keypoint descriptor

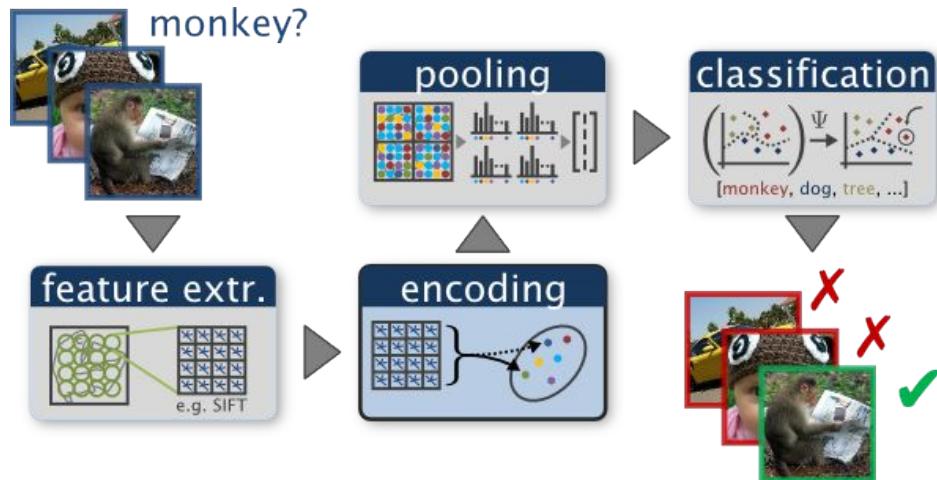

We want to generate a very unique fingerprint for the keypoint. It should be easy to calculate. We also want it to be relatively lenient when it is being compared against other keypoints. To do this, a 16x16 window around the keypoint. This 16x16 window is broken into sixteen 4x4 windows.

First, we create 16x16 window around the image

Then, inside a window we calculate distribution of gradients = 8 features

Classical solutions

Before deep learning era solution for classification task has the following form:

1. Detect SIFT keypoints: find stable local features across scales and rotations.
2. Extract 128-D descriptors for each keypoint.
3. Cluster descriptors (K-means): group all descriptors into clusters → form a visual vocabulary ("visual words").
4. Build Bag-of-Words histogram: for each image count how many descriptors fall into each cluster.
5. Train SVM on histograms: use histograms as feature vectors to classify images.

Neural network solutions

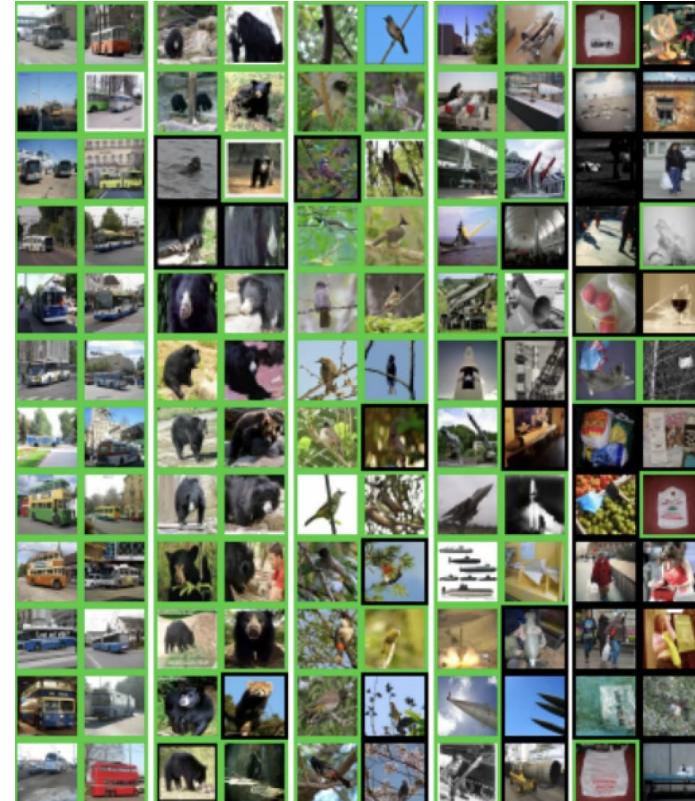

ImageNet

IMAGENET

“Everything in deep learning starts with data”

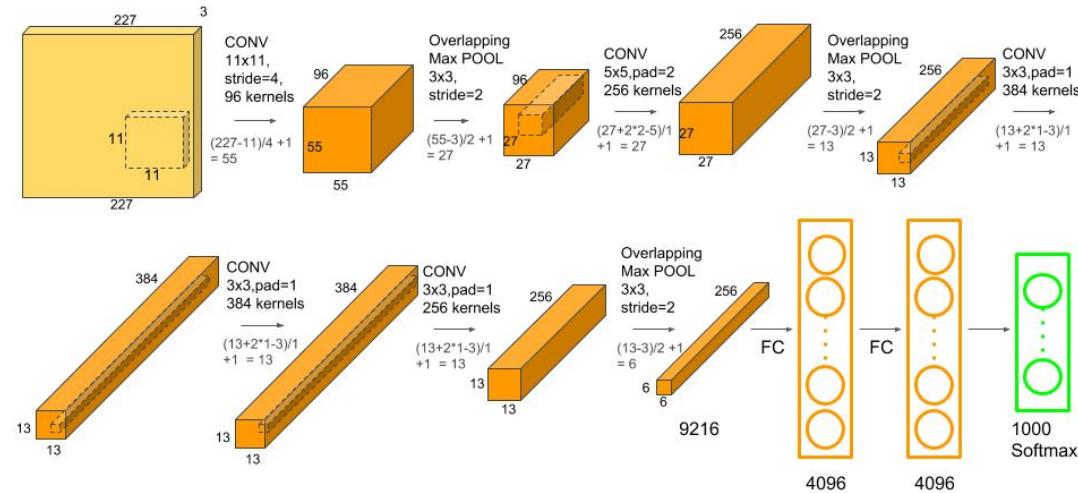

DL in Computer Vision started with ImageNet:

- ImageNet is a dataset of 1.2 M / 50k / 100k images (train/val/test)
- Consists of 1000 different image classes.

[ImageNet: A Large-Scale Hierarchical Image Database \(2009\)](#)

AlexNet

Architecture AlexNet

[Imagenet classification with deep convolutional neural networks \(2012\)](#)

AlexNet: success factors

- Replaced tanh (LeNet-5) with ReLU (x6 speedup)
- Dropout + Augmentations
- 5 conv layers (11x11,5x5,3x3,3x3,3x3)
- LeNet-5 has 2 conv layers
- Test-time augmentations (5 crops x horizontal flip)

Local normalization (analogue to batch normalization)

$$b_{x,y}^i = a_{x,y}^i / \left(k + \alpha \sum_{j=\max(0,i-n/2)}^{\min(N-1,i+n/2)} (a_{x,y}^j)^2 \right)^\beta$$

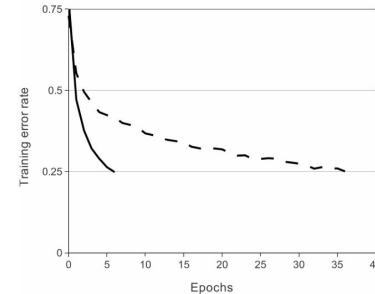

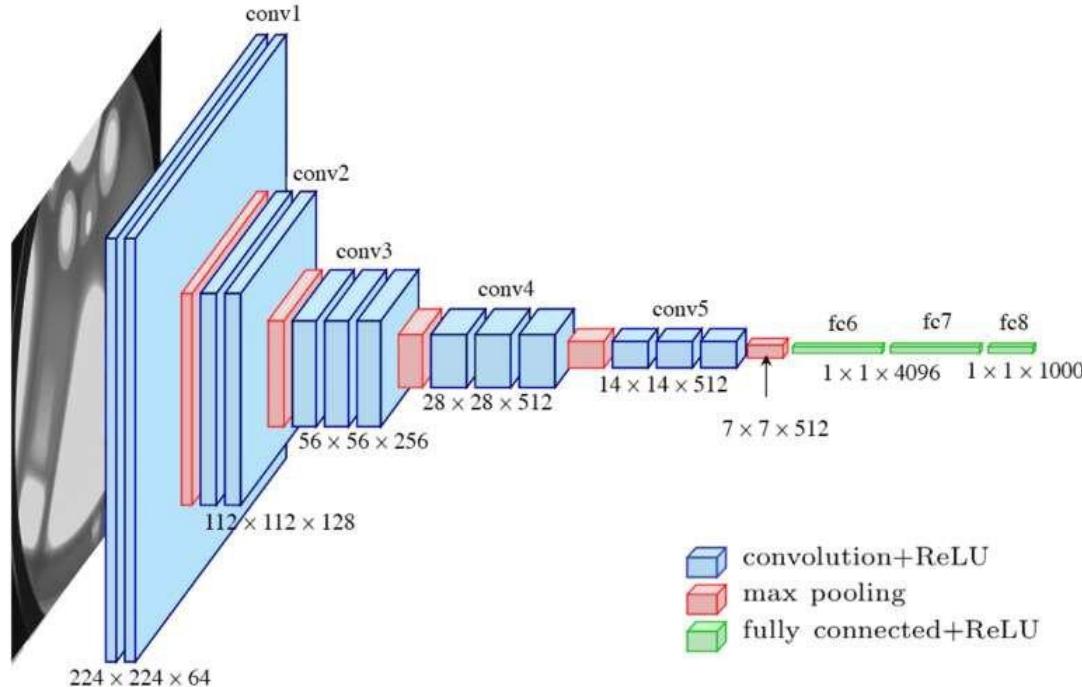

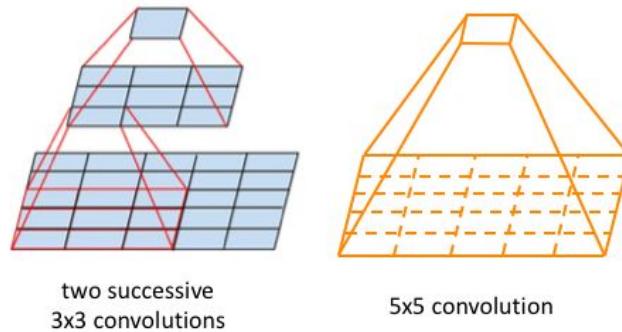

Figure 1: A four-layer convolutional neural network with ReLUs (solid line) reaches a 25% training error rate on CIFAR-10 six times faster than an equivalent network with tanh neurons (dashed line). The learning rates for each network were chosen independently to make training as fast as possible. No regularization of any kind was employed. The magnitude of the effect demonstrated here varies with network architecture, but networks with ReLUs consistently learn several times faster than equivalents with saturating neurons.

VGG

[Very deep convolutional networks for large-scale image recognition \(2015\)](#)

VGG: cascade of kernels

Instead of using, 5x5 conv authors proposed to use two 3x3 conv
It's computationally more efficient (20 params vs 26 params), but the receptive field is equal

VGG: stagewise training

Table 1: **ConvNet configurations** (shown in columns). The depth of the configurations increases from the left (A) to the right (E), as more layers are added (the added layers are shown in bold). The convolutional layer parameters are denoted as “conv(receptive field size)-(number of channels)”. The ReLU activation function is not shown for brevity.

Initial architecture

The final architecture

Instead of training all architecture end-to-end, they created a simple versions of architectures, trained them and added additional layers after the previous stage was completed.

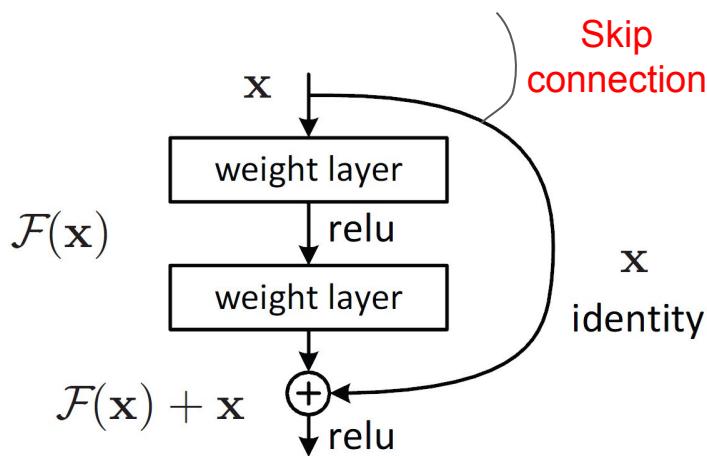

Vanishing gradient problem

Let's draw a little bit

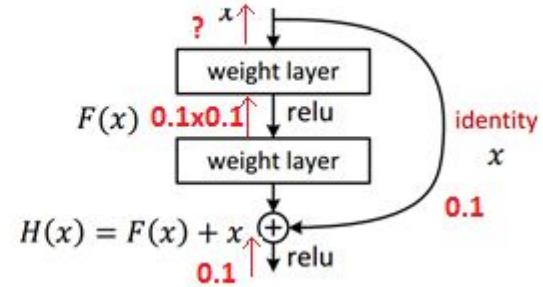

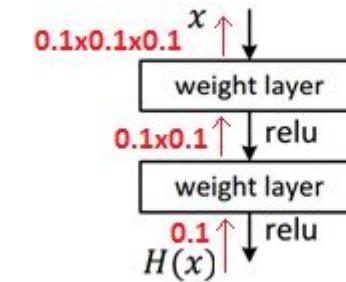

$$\frac{\partial L}{\partial w_1} = \underbrace{\frac{\partial L}{\partial H}}_{\text{grad from output}} \cdot \underbrace{\frac{\partial H}{\partial h_2}}_{\text{grad through layers}} \cdot \underbrace{\frac{\partial h_2}{\partial w_1}}_{\text{grad to weight}}$$

Skip connection

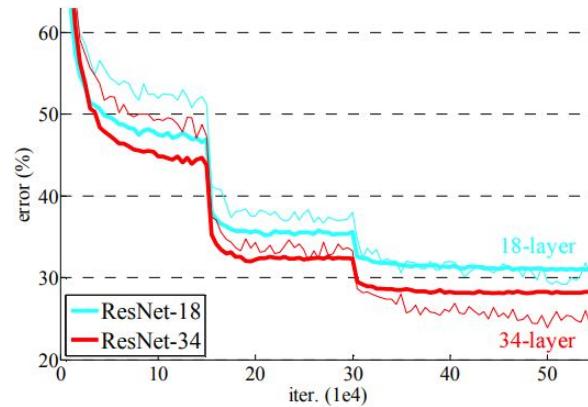

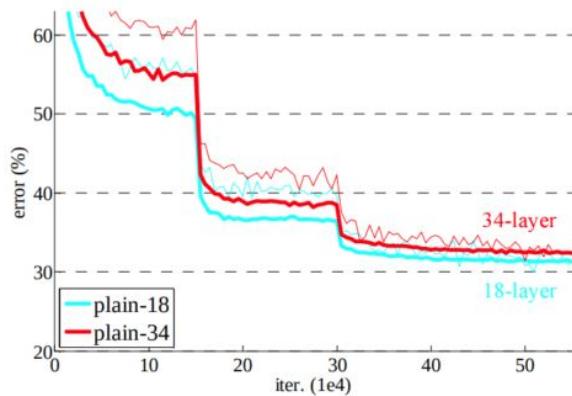

To prevent model from vanishing gradient problem one can use **skip connections**

Creating highway allows to keep the gradient non-saturating + allows to pass information from bottom layer to top.

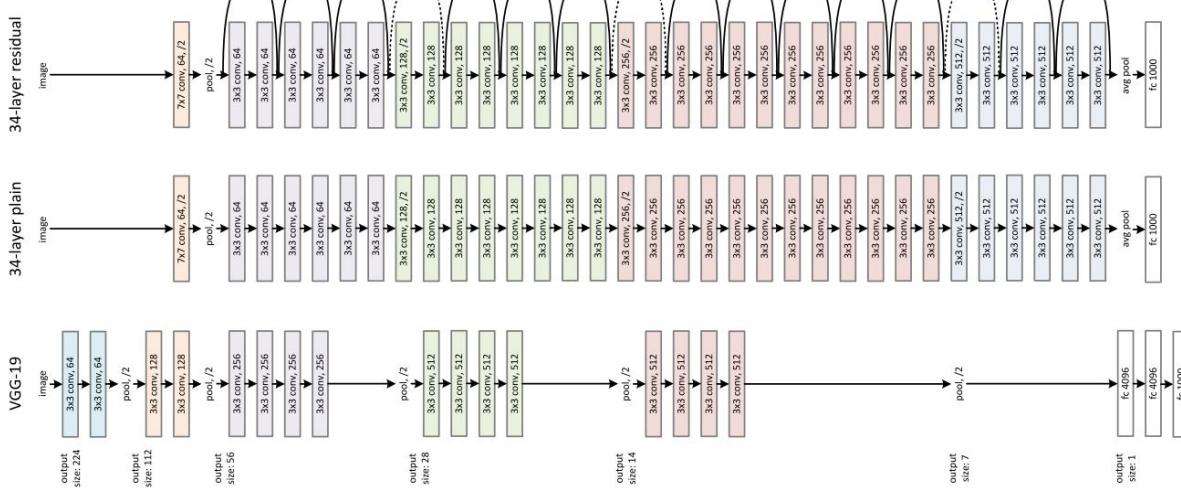

ResNet

The result for base and deep model is the same.

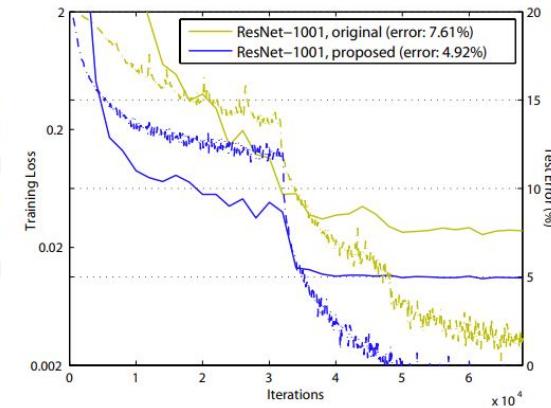

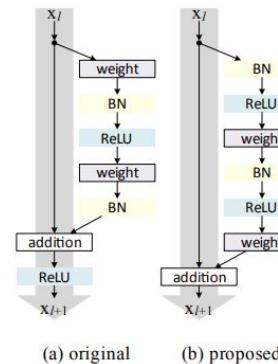

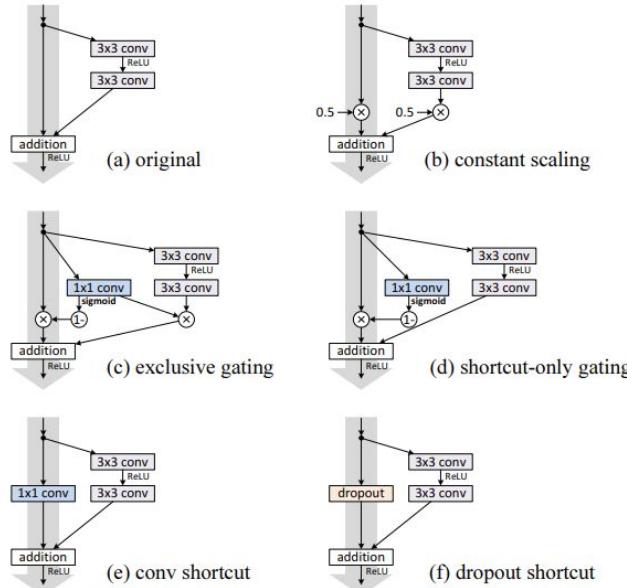

Results for the deeper model are better! Success!

ResNet

ResNet

What is the optimal residual layer form?

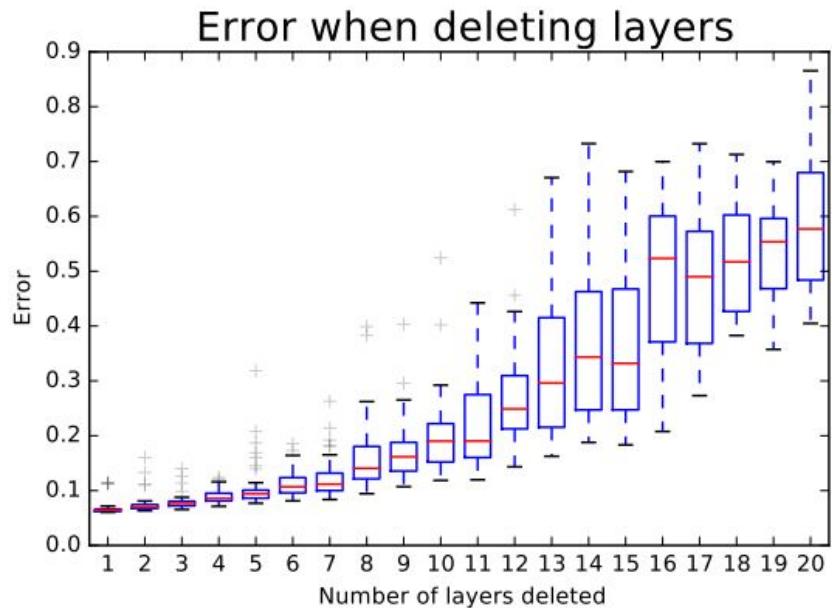

The best strategy for residual connection is $\mathbf{x}_{l+1} = \mathbf{x}_l + \mathcal{F}(\mathbf{x}_l, \mathcal{W}_l)$

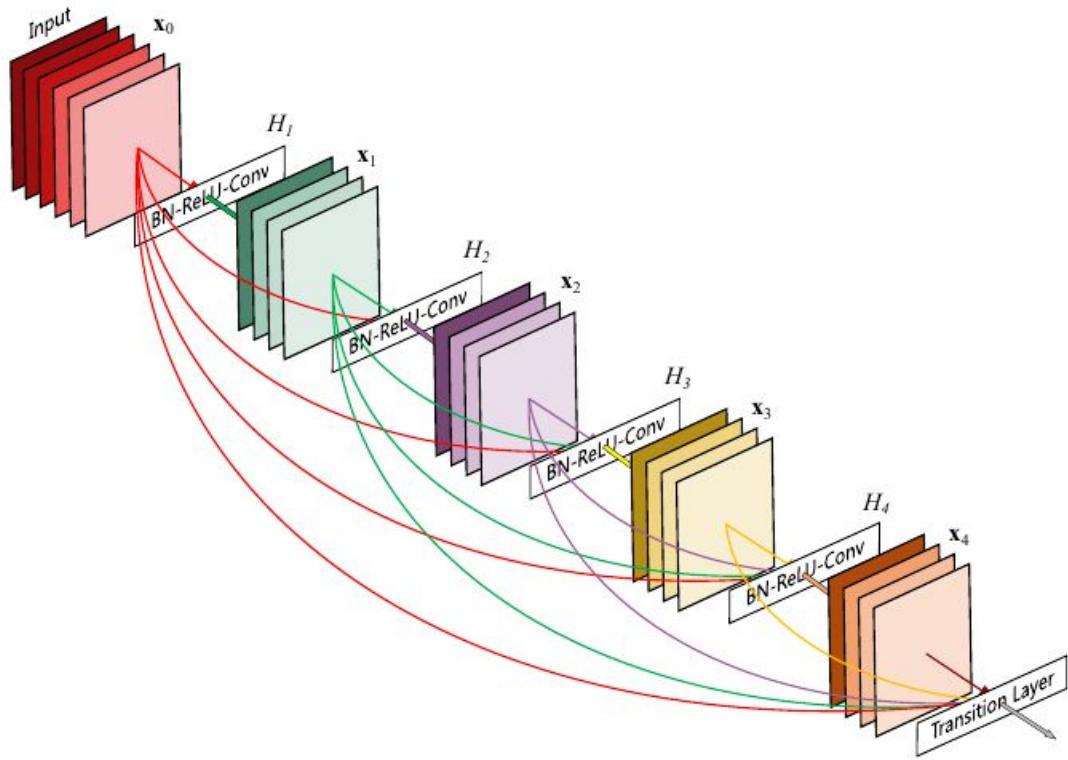

ResNet: cool feature

Interesting fact: ResNet can be a few layers out of ResNet and its performance wouldn't decrease too much.

This is achieved by the fact that ResNet has "workarounds" for information (skip-connection), and if one of them is interrupted, one of them, the information can still pass through the other

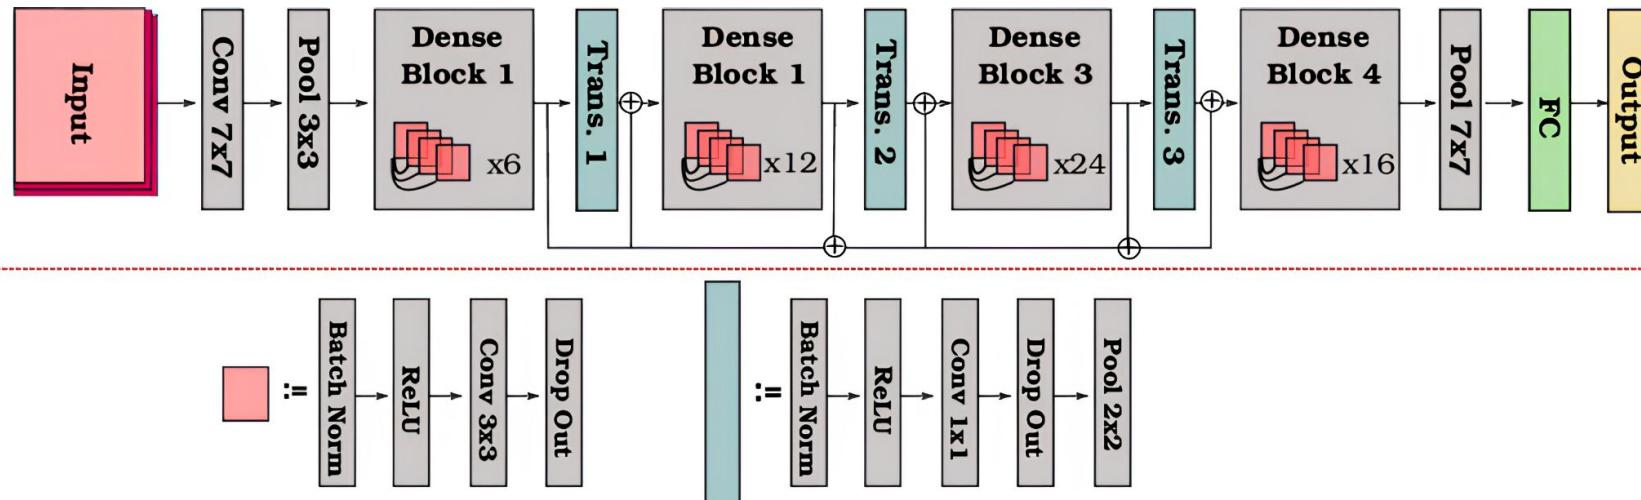

DenseNet

What if each successive layer of the network will receive as input all the outputs of all previous networks previous networks (instead of only one in ResNet)

DenseNet

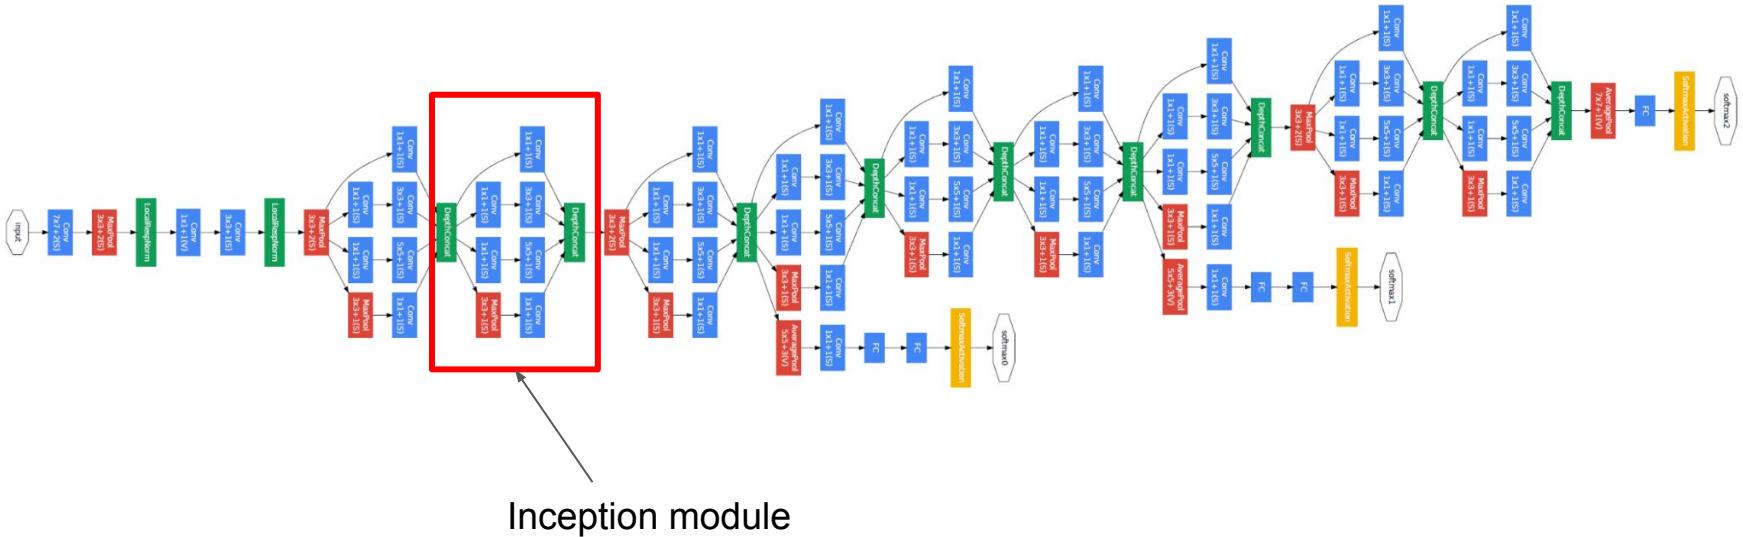

DenseNet

DenseNet

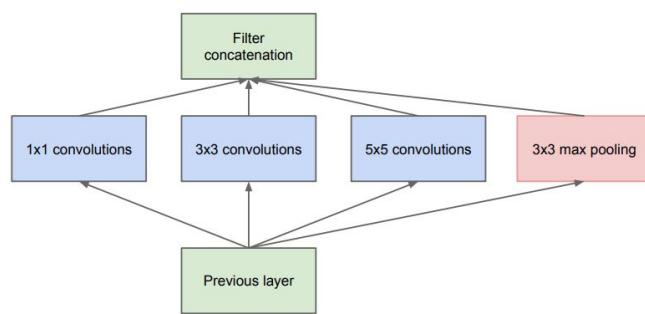

- Strong gradient flow
- The number of layers and parameters is not very large
- Conv layers emphasise a wider variety of features
- Lower conv layers take into account low-complex patterns from higher layers, which can be useful for detecting some low-level patterns.

Inception | GoogLeNet

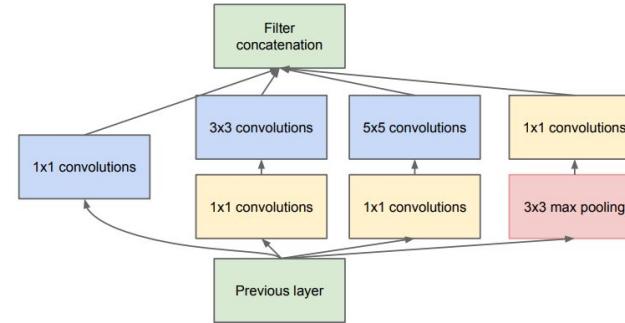

- 22 layer
- Additional outputs for classification

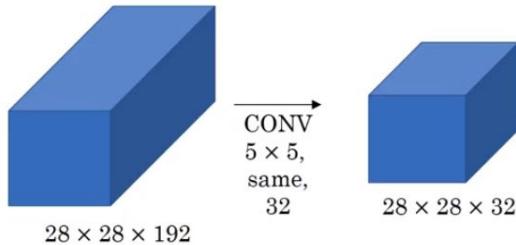

Inception module

(a) Inception module, naïve version

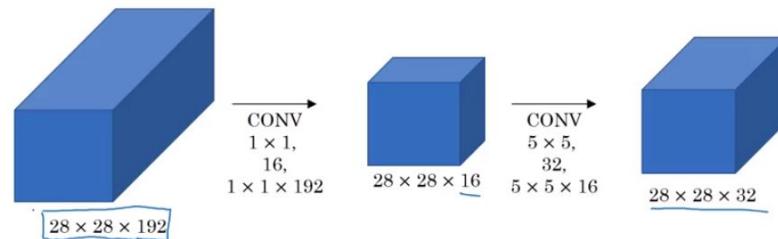

(b) Inception module with dimension reductions

$\approx 120M$ calculations

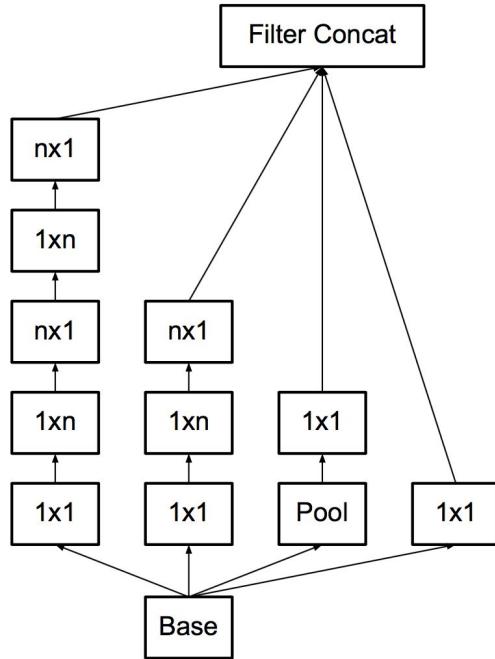

$$\text{FLOPs} = H_{out} \times W_{out} \times C_{out} \times K_h \times K_w \times C_{in}$$

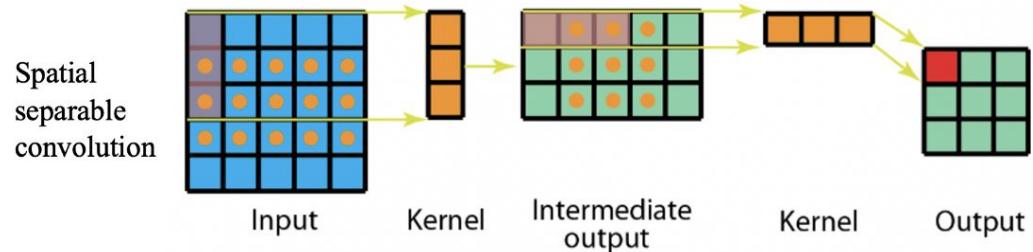

$\approx 12.4M$ calculations

ten times less calculations!

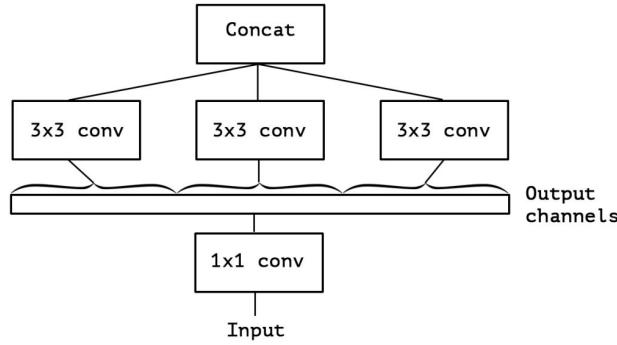

Inception v2, v3

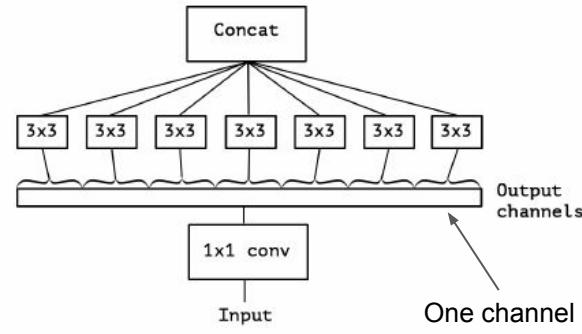

How to represent 3x3 convolution by composition of two one dimensional convolutions?

Xception

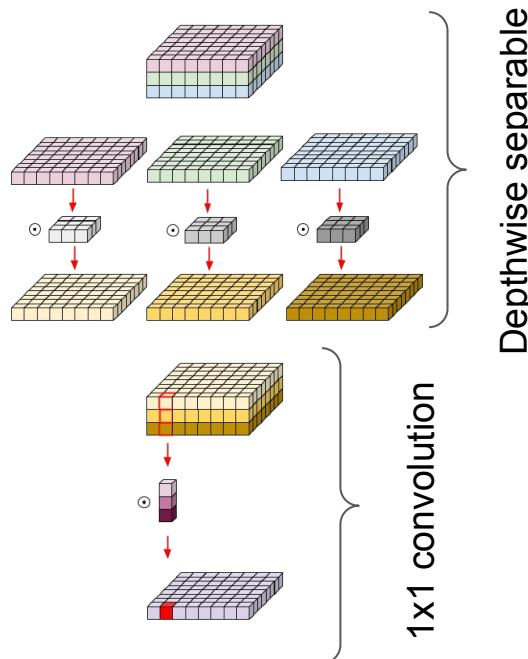

Standardized Inception module form

Xception module

Hypothesis: cross-channel correlations and spatial correlations are sufficiently decoupled that it is preferable not to map them jointly

Xception

How Xception architecture looks like?

Depthwise separable + 1x1 conv
Add residual connections

Table 1. Classification performance comparison on ImageNet (single crop, single model). VGG-16 and ResNet-152 numbers are only included as a reminder. The version of Inception V3 being benchmarked does not include the auxiliary tower.

	Top-1 accuracy	Top-5 accuracy
VGG-16	0.715	0.901
ResNet-152	0.770	0.933
Inception V3	0.782	0.941
Xception	0.790	0.945

MobileConv

Convolution calculations:

$$\text{FLOPs}_{\text{full}} = K^2 \cdot C_{\text{in}} \cdot C_{\text{out}} \cdot H \cdot W$$

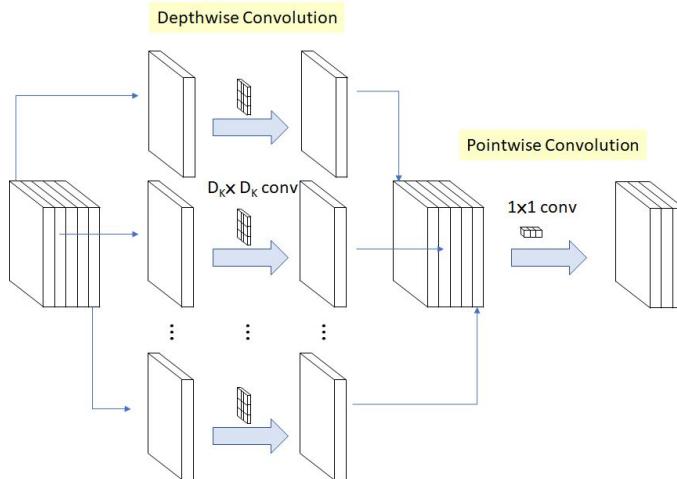

Xception calculations:

$$\text{FLOPs}_{\text{sep}} = K^2 \cdot C_{\text{in}} \cdot H \cdot W + C_{\text{in}} \cdot C_{\text{out}} \cdot H \cdot W$$

$$\frac{\text{FLOPs}_{\text{sep}}}{\text{FLOPs}_{\text{full}}} = \frac{K^2 \cdot C_{\text{in}} \cdot H \cdot W + C_{\text{in}} \cdot C_{\text{out}} \cdot H \cdot W}{K^2 \cdot C_{\text{in}} \cdot C_{\text{out}} \cdot H \cdot W}$$

$$= \frac{1}{C_{\text{out}}} + \frac{1}{K^2}$$

If we take 512 out channels and kernel size $K=3 \rightarrow$ we get approximately 9 times less calculations

MobileNet

Table 1. MobileNet Body Architecture

Type / Stride	Filter Shape	Input Size
Conv / s2	$3 \times 3 \times 3 \times 32$	$224 \times 224 \times 3$
Conv dw / s1	$3 \times 3 \times 32$ dw	$112 \times 112 \times 32$
Conv / s1	$1 \times 1 \times 32 \times 64$	$112 \times 112 \times 32$
Conv dw / s2	$3 \times 3 \times 64$ dw	$112 \times 112 \times 64$
Conv / s1	$1 \times 1 \times 64 \times 128$	$56 \times 56 \times 64$
Conv dw / s1	$3 \times 3 \times 128$ dw	$56 \times 56 \times 128$
Conv / s1	$1 \times 1 \times 128 \times 128$	$56 \times 56 \times 128$
Conv dw / s2	$3 \times 3 \times 128$ dw	$56 \times 56 \times 128$
Conv / s1	$1 \times 1 \times 128 \times 256$	$28 \times 28 \times 128$
Conv dw / s1	$3 \times 3 \times 256$ dw	$28 \times 28 \times 256$
Conv / s1	$1 \times 1 \times 256 \times 256$	$28 \times 28 \times 256$
Conv dw / s2	$3 \times 3 \times 256$ dw	$28 \times 28 \times 256$
Conv / s1	$1 \times 1 \times 256 \times 512$	$14 \times 14 \times 256$
5× Conv dw / s1	$3 \times 3 \times 512$ dw	$14 \times 14 \times 512$
	$1 \times 1 \times 512 \times 512$	$14 \times 14 \times 512$
Conv dw / s2	$3 \times 3 \times 512$ dw	$14 \times 14 \times 512$
Conv / s1	$1 \times 1 \times 512 \times 1024$	$7 \times 7 \times 512$
Conv dw / s2	$3 \times 3 \times 1024$ dw	$7 \times 7 \times 1024$
Conv / s1	$1 \times 1 \times 1024 \times 1024$	$7 \times 7 \times 1024$
Avg Pool / s1	Pool 7×7	$7 \times 7 \times 1024$
FC / s1	1024 × 1000	$1 \times 1 \times 1024$
Softmax / s1	Classifier	$1 \times 1 \times 1000$

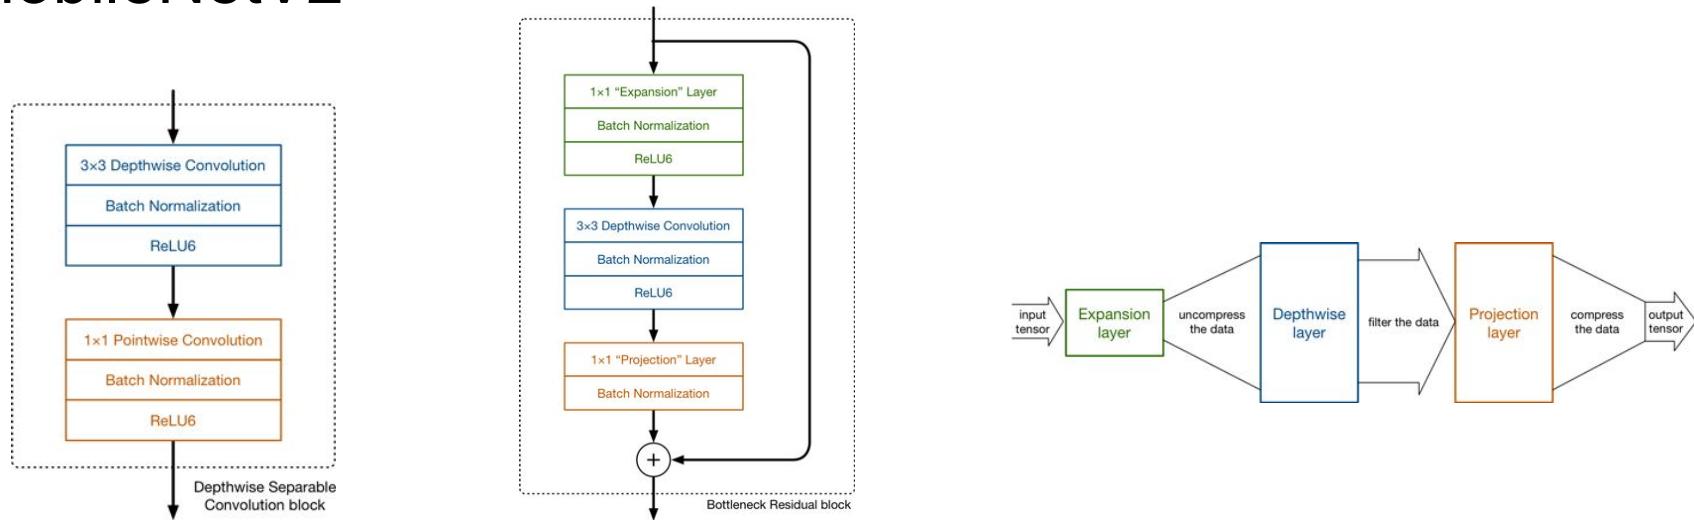

Got rid of all the overhead (no residual connections); the goal is not to match Xception accuracy, but to achieve an extremely lightweight model.

Table 8. MobileNet Comparison to Popular Models

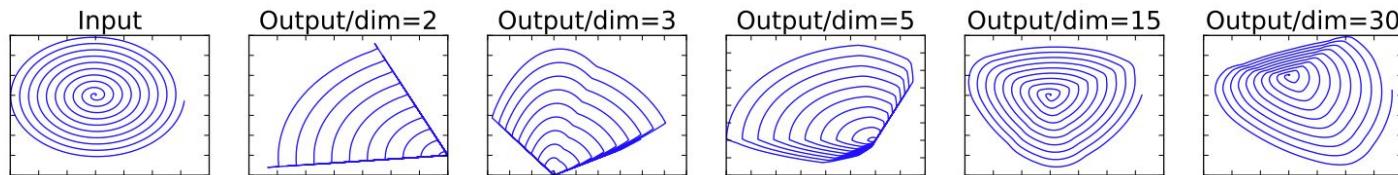

Model	ImageNet	Million	Million
	Accuracy	Mult-Adds	Parameters
1.0 MobileNet-224	70.6%	569	4.2
GoogleNet	69.8%	1550	6.8
VGG 16	71.5%	15300	138

Same quality but number of calculations and number of parameters ~1.5 times less

MobileNetV2

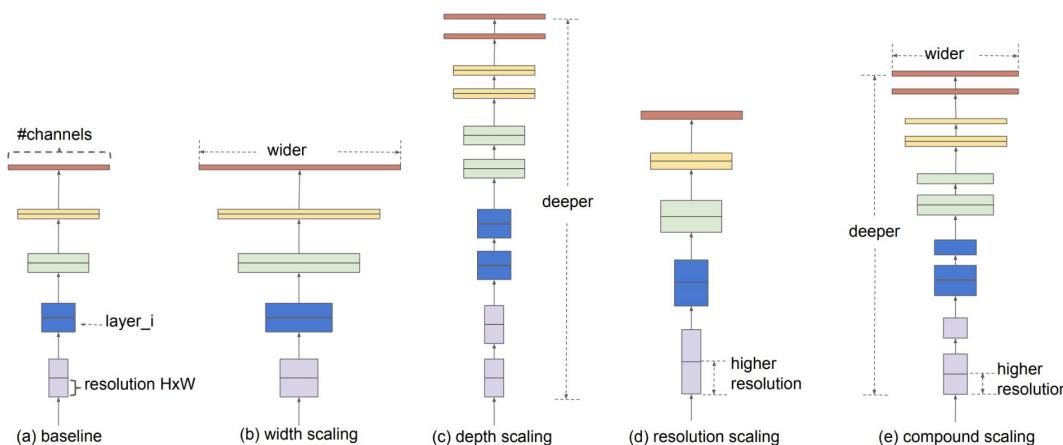

ReLU in low dimension can kill a lot of information

EfficientNet

We can improve quality of the model by increasing resolution/depth/width of the model. What is the optimal balance between them?

$$\text{depth: } d = \alpha^\phi$$

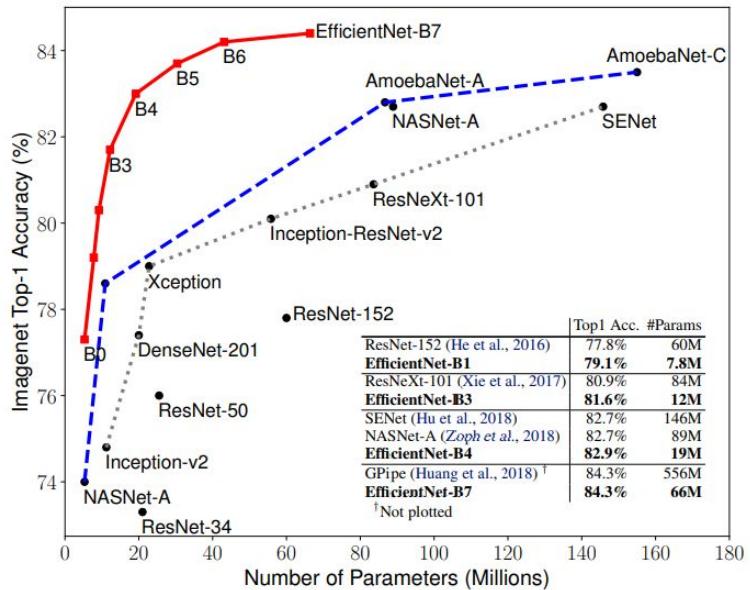

$$\text{width: } w = \beta^\phi$$

$$\text{resolution: } r = \gamma^\phi$$

$$\text{s.t. } \alpha \cdot \beta^2 \cdot \gamma^2 \approx 2$$

$$\alpha \geq 1, \beta \geq 1, \gamma \geq 1$$

EfficientNet

EfficientNet problems

1. When large image resolution was used to train the large models, the training was slow.
2. In the early layers of the network architecture, depthwise convolution layers (MBConv) were slow. Depthwise convolutional layers generally have fewer parameters than regular convolutional layers, but the problem is that they cannot fully make use of modern accelerators.
3. Equal scaling was applied to the height, width, and image resolution to create the various EfficientNet models from B0 to B7. This equal scaling of all layers is not optimal.

EfficientNetV2

Adding a combination of MBConv and Fused-MBConv blocks

MBConv block often cannot fully make use of modern accelerators. Fused-MBConv layers can better utilize server/mobile accelerators.

NAS search to optimize Accuracy, Parameter Efficiency, and Training Efficiency

Intelligent Model Scaling

- i. maximum image size was restricted to 480x480 pixels to reduce GPU/TPU memory usage, hence increasing training speed.
- ii. more layers were added to later stages, to increase network capacity without increasing much runtime overhead.

Progressive Learning

The idea is very simple. In the earlier steps, the network was trained on small images and weak regularization. This allows the network to learn the features fast. Then the image sizes are gradually increased, and so are the regularizations.

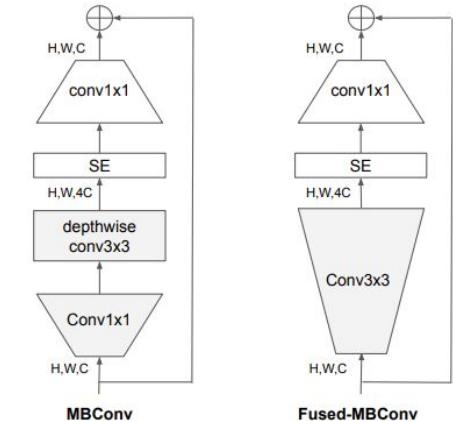

Figure 2. Structure of MBConv and Fused-MBConv.

ViT: Vision Transformer

<https://nn.labml.ai/transformers/vit/index.html>

ViT: Patching

How to adapt transformer for computer vision? First thing to deal with is attention. If we consider one pixel as a token we have our attention matrix will have size $(500 \times 500)^2$ which is huge. So, the authors proposed to slice image on patches and work with them.

1) Slice

2) Unfold

```
from einops import rearrange  
  
p = patch_size # P in maths  
  
x_p = rearrange(img, 'b c (h p1) (w p2) -> b (h w) (p1 p2 c)', p1 = p, p2 = p)
```

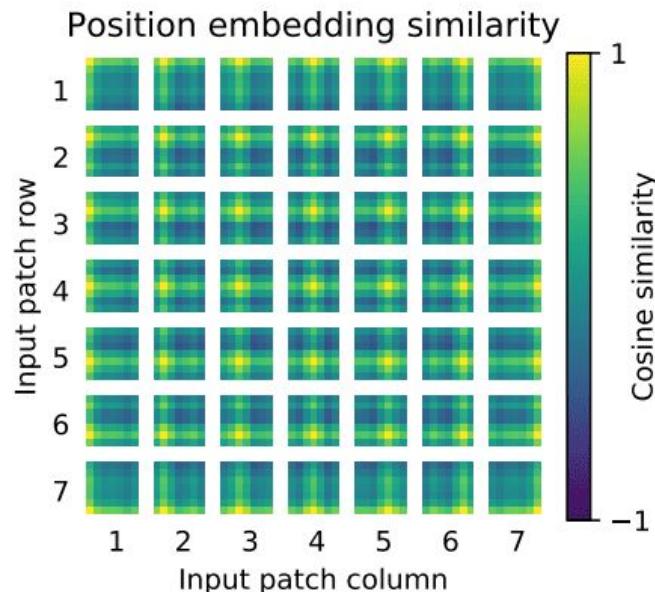

Code to implement this operation

ViT: Positional embeddings

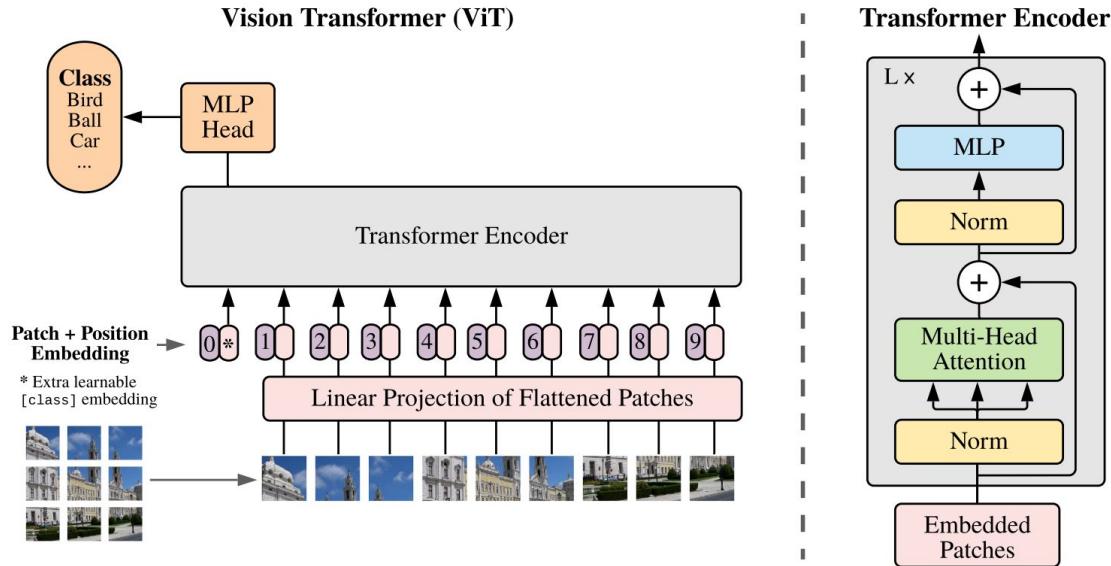

As in transformers in NLP we have to add positional information to embeddings. But the images have 2D positional information (x, y).

Authors tried both 2D positional and sum of two 1D positional embeddings. The latter works with the same quality. And indeed the learned positional matrix looks at neighbourhood pixels.

To fine-tune in higher resolutions, 2D interpolation of the pre-trained position embeddings is performed.

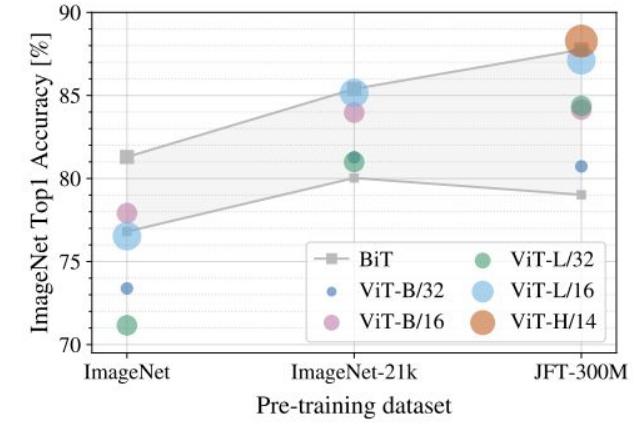

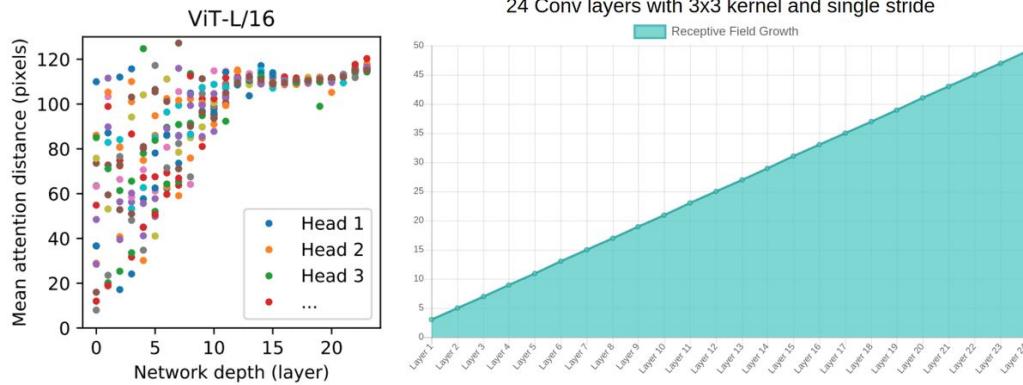

ViT: architecture

An image is worth 16x16 words: transformers for image recognition at scale (2021)

ViT: benefits

- 1) ViT has a global perception field in contrast of CNN. And from the figure we can see what model start to use this opportunity from the beginning

- 2) ViT continues to scale with data, CNN doesn't
